

ABSTRACT

A system saves browsed data in a database in response to a user request by assigning a predetermined index to the data, wherein the user is not requested for any index. The 5 system sorts indices of the data in the database and displays the sorted indices, then the system retrieves, in response to a selection of an index from the displayed indices by a user, the data corresponding to the selected index from the database. Accordingly if a user wants to save a data currently browsed, he can make store the data in the database easily only by issuing an instruction to save without specifying any index.
